

Network Security - Server Security - Domain Security

Protecting your data and hardware from both internal and external threats is very important for all companies. We can implement intranet security policies, content-based firewall configuration, port blocking, throttling, and monitoring across the network.

Many small businesses do not have a proper firewall to protect their business network. Many times they self-install a wireless router without the notion of how to properly secure the wireless network. Network security is often overlooked or under protected with residential type network routers purchased at the local electronics store. Don't treat your business network as a home network! And possibly (inadvertently) allow access to your business secrets! Let us assist in implementing a proper enterprise level router, firewall, wireless router (like SonicWall, WatchGuard, Barracuda, or Cisco) to protect your business network.

Server security and domain security is another subject that is often tossed aside in the name of convenience. Often it is viewed as a hassle or hindrance to have to remember passwords or deal with restricted access. Don't be fooled. Keep your data secured under "lock and key". Secure your server and domain, and restrict access to only those that require it. Let us assess and implement a properly secured domain server or secured file server.
